Fullerene Oxidation anti-Bredt olefin Electrophilic addition to olefin

The mCPBA oxidation of methano-bridged [5,6] open fulleroid 1 anomalously resulted in the selective electrophilic addition at the bridgehead anti-Bredt double bond rather than the usual epoxidation. The mechanistic preference for the unprecedented stepwise addition of mCPBA vs the concerted epoxidation was explained in terms of the notable π-orbital misalignment (>30°) based on the B3LYP/6-31G(d) level calculation.

Although fullerenes are well known as electrophiles due to the low-lying LUMO orbitals,1 they can also behave as nucleophiles in some chemical modifications such as epoxidation2 with m-chloroperbenzoic acid (mCPBA). The fullerene epoxides are useful reactive intermediates in the synthesis of regioselective bis-adducts3 and fullerene dimer.4 However, the control of reaction conditions to selectively give monoepoxide has been a challenging task because of the presence of a number of reactive [6,6] bonds in spherical fullerenes. In fact, the reaction of C60 with mCPBA gives a mixture of monoepoxide and various multiepoxides, from which it is difficult to separate each of them. We are interested in the reactivity of [5,6] open fulleroid1,6 1 with highly-twisted bridgehead double bonds7 as a useful synthetic entity to develop a new regioselective synthetic methodology in fullerene chemistry. Fulleroiids are known as homofullerenes still retaining 60π-electron system and to exhibit the regioselective Zn(Cu) catalyzed hydrogenation8 and photooxygenation with singlet oxygen9 at the bridgehead olefin.

In our recent study on the comparative reactivity of the [5,6] open fulleroiids vs C60, we have found the noticeably enhanced reactivity of the fulleroiids at the bridgehead double bonds in Diels–Alder reaction with some flexible 1,3-dienes.10 It was also expected that the higher π-orbital misalignment angle τ (−30°), 8,10 as compared to the usual anti-Bredt olefins (10–20°, vide infra), would result in a dramatic change in the reactivity mode. These situations prompted us to investigate the mCPBA oxidation of fulleroiids with the aim of bringing about the regioselective epoxidation. In this paper, we would like to report the unprecedented electrophilic addition of mCPBA to the anti-Bredt olefin of the fulleroid 1 as shown in Scheme 1 and discuss the mechanistic feature on the basis of the B3LYP/6-31G(d) calculation.

**Scheme 1** Electrophilic addition of mCPBA to fulleroid

Methano-bridged fulleroid 1 was prepared by the literature methods.11,12 The oxidation of 1 with mCPBA (10 equiv.) at 30 °C gave several oxidized products, as seen in the HPLC chart of the reaction mixture (Figure 1a). The APCI-LCMS measurement showed the sharp peak of the residual 1 along with the following broad peak consisting of a mixture of 1:1 adduct (1+mCPBA: m/z = 906) and its fragment (m/z = 751, 1+OH+) (Figure 1b). The

preceding shoulder fraction overlapped with 1 seems to be monoepoxide (m/z = 922) of the 1:1 adduct and its fragment (m/z = 767) (Figure 1c).

The portion of 1:1 adduct was successfully fractionated by silica gel column chromatography (15.4 mg; 15% isolated yield). The purity was verified by HPLC (Figure S1). The isolated product showed the characteristic IR absorption at 1727 cm⁻¹ assignable to the benzoate ester group. Unfortunately, this fraction was still the regioisomeric mixture (major/minor = 3) of 1:1 adducts 2a/2b by ¹H NMR spectrum (Figure 2). Although an attempt to separate and assign these region-isomers was failed, we tentatively assign 2a to the major isomer according to the calculation (vide infra). However, the 1,2-addition at the bridgehead double bond was undoubtedly evidenced by the following facts. (1) The significant down-field shift (1.6–2.3 ppm) of the methano-bridged H(b) was found for the major (δ = 5.2 ppm, Figure S2) and for the minor (4.5, respectively, as compared to that of parent 1 (2.9). These shifts were clearly explained by the reduction of the shielding effects of underlying hexagonal triene ring by 1,2-addition of mCPBA. (2) The 2D HMBC correlation is observed (Figure S3) between each of the bridged H(a)/H(b) and the OH or m-chlorobenzoate (mCB)-substituted remote sp³-carbon (Cα, red circle). (3) The existence of NOE interaction between the hydroxy proton H(g) and the magnetically isolated o-proton H(f) would support the formation of 1,2-adducts (Figure S4). However, there is no NOE enhancement between the bridged CH₂ and any proton of the mCB group, indicating the less congested outward orientation of mCB moiety.

This electrophilic esterification of fulleroid by mCPBA is unprecedented and markedly contrast to the usual epoxidation of C₆₀ as well as the common olefins. It is likely that the highly twisted double bond of 1 plays a crucial role in the present 1,2-addition of mCPBA. Then, we calculated its transition state (TS) and intrinsic reaction coordinate (IRC) with B3LYP/6-31G(d) level (Figure 3) in order to gain a mechanistic insight into the mCPBA oxidation of 1. The results showed the asymmetric transition state TS-1 (Figure 3a) in which the relevant OH group is located more closer to the bridgehead Cα than to the adjacent Cβ carbon and then leads to the ionic intermediate 1aOH⁺ (Figure 3b). On the other hand, the asymmetric approach of mCPBA to the Cβ carbon would generate the energetically higher transition state TS-2 and provide the less stable intermediate 1bOH⁺ (Figure 3c,d), in conformity with the minor 2b. Although the energy difference (3.8 kcal/mol) between TS-1 and TS-2 is larger than the value deduced from the experimental product ratio (3:1), this may be ascribed to the several reasons. The appreciable difference in HOMO orbital coefficients of the anti-Bredt double...
bond moiety is also likely responsible for such an asymmetric electrophilic attack (Figure S6). These two pathways can be terminologically categorized as bimolecular electrophilic addition (AdE-2).

Figure 3. Relative energy vs the reaction coordinate (translated to the distance between C8 or C9) and O2m, for TS-1 or TS-2, respectively, obtained from TS and IRC calculations. (a) Geometry of the TS-1 of 1 + mCPBA reaction (Imaginary freq. = 504 cm⁻¹, dipole moment (µ) = 3.6 D). (b) Geometry of the 1aOH⁺ and m-chlorobenzoate (mCB⁻) obtained from the IRC calculation (not optimized structure).¹⁷ (c) Geometry of the TS-2 of 1 + mCPBA reaction (Imaginary freq. = 496 cm⁻¹, µ = 5.4 D). (d) Geometry of the 1bOH⁺ and m-chlorobenzoate (mCB⁻) obtained from the IRC calculation (not optimized structure).¹⁷ These geometries and energies were calculated by B3LYP/6-31G(d) level without solvation parameter. The yellow balls denote the cycloheptatriene ring.

To verify whether the present calculations are reasonable, we have compared our results with those of the previously reported mCPBA oxidation of olefins.¹⁹⁻²¹ Though the reported studies have mainly concerned the simple and less twisted alkenes, two reaction pathways have been proposed; one is the generally accepted concerted process via a butterfly-like symmetrical transition state (route (a) in Scheme 2)¹⁵ and another is the stepwise process via asymmetric transition state and the ionic intermediate,²⁰ similar to the present calculation (route (b) in Scheme 2). While the higher level calculations¹⁹ and the detailed investigation of isotope effect¹⁵ made supported the concerted mechanism, our results indicated that twisted olefin prefers the route (b),²² probably because the highly twisted π-orbital could not perform the symmetrical orbital interaction with mCPBA as in route (a). The generated intermediate 1aOH⁺ undergoes the addition of m-chlorobenzoate (mCB⁻), rather than the ring-closure to epoxide. Indeed, the intervention of such intermediate was proved by formation of the crossover p-methyl benzoate adduct (m/z = 886) when p-toluic acid coexists (route (c) in Scheme 2 and Figure S7).

One question is raised why mCPBA oxidation of several anti-Bredt olefins²³ exclusively gave the epoxides. The π-orbital misalignment angle (γ) (15.7° for bicyclo[3.3.1]non-1-ene, calculated by B3LYP/6-31G*) is considerably smaller than those of the fulleroids (>30°).⁵,¹⁰ The calculation for the bicyclic compound provided rather symmetrical TS (Figure S8) in accord with the actual epoxidation, implying that even anti-Bredt olefins allow the symmetric TS via route (a), when γ is not so large.

In conclusion, we have found that the methano-bridged [5.6]open fulleroid 1 underwent the stepwise bimolecular electrophilic addition (AdE₂) of mCPBA at the twisted bridgehead double bond to afford the regiosomeric mixture of α-hydroxyfullereryl m-chlorobenzoates. This unusual addition was rationalized by the larger torsional angle of double bond (γ ~ 30°), which would inhibit the symmetric TS (so-called butterfly TS) generally argued for the concerted epoxidation of olefins.

Supporting Information Available Experimental procedure, NMR of 2a+2b, DFT calculation for 2a and 2b, crossover experiment with p-toluic acid, transition state calculation of bicyclo[3.3.1]non-1-ene, and full citation of Gaussian 09.

such selective photooxygenation was also reported forazafuleroids. See (a): Hummel, J. C.; Prato, M.;

1aOH and 1bOH were not calculated their optimized geometries, because of the absence of solvent parameter on the calculation to stabilize such zwiterionic state.

No isomerization reaction was observed between 2a and 2b on 2 days standing at 25 °C in CDCl3, as confirmed by the NMR measurement. Incidentally, compound 2a was 3.4 kcal/mol more stable than 2b by DFT calculation (Figure S5). One reason for the inconsistency between the differential TS energy and the isomer ratio may be the absence of entropy term (AS‡) on the present calculation in addition to the lack of solvation parameter. One can also conceive that the solvent toluene (μ = 0.375 D) from CRC Handbook of Chemistry and Physics 91st Ed.) will more stabilize the polar TS-2 (μ = 5.4 D) than TS-1 (μ = 3.6 D), thus reducing the differential isomer ratio of 2a/2b.

13. Reaction procedure and spectral data of the regioisomeric mixture of 2a and 2b. mCPBA (386 mg, 2.23 mmol) and I (82.1 mg, 0.112 mmol) were dissolved in toluene. The solution was stirred overnight at 30 °C, and the progress of reaction was traced by HPLC (buckycrp). The reaction mixture was concentrated and submitted to silica gel column chromatography (toluene/hexane) to give 15.4 mg of 2a/2b mixture (0.017 mmol, conversion yield is 24% and isolated yield is 15%) and recovered 1 (29.4mg) and byproduct (8 mg). 1H NMR (600 MHz, CD3OD, δ, 1H): Major isomer: δ 5.06 (s, 1H), 5.20 (d, J = 11.4 Hz, 1H), 5.59 (d, J = 11.4 Hz, 1H), 7.56 (t, J = 8.4, 7.8 Hz, 1H, overlapped with minor), 7.67 (d, J = 7.8 Hz, 1H, overlapped with minor), 8.18 (d, J = 8.4 Hz, 1H), 8.24 (s, 1H); Minor isomer: δ 4.56 (s, 1H), 4.62 (d, J = 11.4 Hz, 1H), 5.13 (d, J = 11.4 Hz, 1H), 7.56 (t, J = 8.4, 7.8 Hz, 1H, overlapped with major), 7.67 (d, J = 7.8 Hz, 1H, overlapped with major), 8.31 (d, J = 8.4 Hz, 1H), 8.40 (s, 1H). 13C NMR (150 MHz, CD3OD, δ, 1H): CDCl3 = 31δ 32.7(s, CH2), 85.7(s, C), 94.6(s, C), 127.8(s, CH), 130.0(s, CH), 130.3(s, CH), 134.0(s, CH), 163.3(s, C=O), except for the signals assigned to the fulleroi sp2 carbons (125–155 ppm. See Figure S2). HRMS (FAB–MS): Calcd for C60H48O6Cl 906.0894. Found 906.0112.

14. The low isolated yield (15%) of the 1:1 addsucts 2a/2b is mainly due to the incompletion of the reaction (to avoid further epoxidation) as well as the column chromatographic isolation.

15. DFT calculations were carried out with Gaussian 09 program. Its full citation is shown in Supporting Information.

16. Both these cationic intermediates 1aOH and 1bOH were not calculated their optimized geometries, because of the absence of solvent parameter on the calculation to stabilize such zwiterionic state.

17. No isomerization reaction was observed between 2a and 2b on 2 days standing at 25 °C in CDCl3, as confirmed by the NMR measurement. Incidentally, compound 2a was 3.4 kcal/mol more stable than 2b by DFT calculation (Figure S5). One reason for the inconsistency between the differential TS energy and the isomer ratio may be the absence of entropy term (AS‡) on the present calculation in addition to the lack of solvation parameter. One can also conceive that the solvent toluene (μ = 0.375 D) from CRC Handbook of Chemistry and Physics 91st Ed.) will more stabilize the polar TS-2 (μ = 5.4 D) than TS-1 (μ = 3.6 D), thus reducing the differential isomer ratio of 2a/2b.

18. Although our calculational method (DFT/B3LYP) is relatively rough as compared to the previous theoretical calculations (such as QCISD in ref. 19a), these higher calculations cannot be straightforwardly applied to fulleroi with too many atoms and electrons. Multi-layered method such as ONIOM will enable such higher level calculation to fulleroi, as the following recent ONIOM application to the Diels–Alder reaction of fulleroi.
